At $x = ct$ $\frac{dy}{dx} = -\frac{c^2}{c^2 t^2} = -\frac{1}{t^2}$ Equation of the tangent at T is: $y - \frac{c}{t} = -\frac{1}{t^2}(x - ct)$ $yt^2 - ct = -x + ct$ or $x + t^2 y = 2ct$ (ii) Similarly the equation of the tangent at Q and P are $x + p^2 y = 2cp \quad (1)$ $x + q^2 y = 2cq$ $y(p^2 - q^2) = 2c(p - q)$ $y = \frac{2c}{p + q} \quad \text{sub into (1)}$ $\Rightarrow x = 2cp - \frac{2cp^2}{p + q}$ $= -\frac{2cpq}{p + q}$ Since $pq = 1$ $x = \frac{2c}{p + q}$ $\therefore R\left(\frac{2c}{p + q}, \frac{2c}{p + q}\right)$ Hence the locus of R is the line $y = x$ Where $-c < x < 0$ and $0 < x < c$, since $pq = 1$. (a) Let $A = x + y$ and $B = x - y$	1	
--	----------	--

$\therefore A + B = 2x \Rightarrow x = \frac{A+B}{2}$ $A - B = 2y \Rightarrow y = \frac{A-B}{2}$ $\therefore \sin A + \sin B = 2 \sin \frac{A+B}{2} \cos \frac{A-B}{2}$ and $\cos A + \cos B = 2 \cos \frac{A+B}{2} \cos \frac{A-B}{2}$ $\frac{\sin A + \sin B}{\cos A + \cos B} = \frac{2 \sin \frac{A+B}{2} \cos \frac{A-B}{2}}{2 \cos \frac{A+B}{2} \cos \frac{A-B}{2}} \quad (1)$ $= \tan \frac{A+B}{2}$ Now $A + B + C = \pi$ $\therefore A + B = \pi - C$ $\therefore \tan \frac{A+B}{2} = \tan \frac{\pi - C}{2}$ $R.H.S = \tan \left(\frac{\pi}{2} - \frac{C}{2} \right)$ $= \cot \frac{C}{2}$ $= L.H.S \quad \text{from (1)}$ (b) (i) $f'(x) = \frac{x \cos x - \sin x}{x^2}$ $= \frac{x \cos x - \cos x \tan x}{x^2}$ $= \frac{\cos x (x - \tan x)}{x^2}$	expressing x and y in term of A & B 1 correct simplifying 1 Correct answer 1 Correct differentiation

$$x^2 > 0, \cos x > 0 \text{ and } \tan x > x \text{ for } 0 < x < \frac{\pi}{2}$$

$$\therefore x - \tan x < 0, \text{ hence } f'(x) < 0$$

(ii)

$f(x)$ is a decreasing function for $0 < x < \frac{\pi}{2}$ as proven above.

$$f\left(\frac{\pi}{2}\right) = \frac{2}{\pi} \text{ and } f(0) = 1$$

From the graph $f(x) \geq \frac{2}{\pi}$ for $0 \leq x \leq \frac{\pi}{2}$

$$\text{ie } \frac{\sin x}{x} \geq \frac{2}{\pi}$$

$$\therefore \sin x \geq \frac{2x}{\pi}$$

(c) (i)

$$w = \text{cis } \frac{2\pi}{7}$$

$$\therefore w^7 = \left(\text{cis } \frac{2\pi}{7} \right)^7$$

$$= \text{cis } 2\pi$$

$$= 1$$

correct reason

1
correct graph

1
correct reason

1
expressing w^7 as $\text{cis } 2\pi$

$\therefore w$ is a root of $x^7 - 1 = 0$, that is of
 $(x-1)(x^6 + x^5 + \dots + 1) = 0$

Since $w \neq 1$, then w satisfy $x^6 + x^5 + \dots + 1 = 0$

$$\therefore 1 + w + w^2 + \dots + w^6 = 0$$

(ii)

Since the quadratic equation $x^2 + ax + b = 0$ has real coefficients therefore complex roots are conjugate.

Hence $\bar{w}$ is also a root.

$$\therefore \beta = \bar{\alpha} = \bar{w} + \bar{w}^2 + \bar{w}^4$$

Since $\bar{w} = w^6$, $\bar{w}^2 = w^5$, $\bar{w}^4 = w^3$ from the diagram

$$\beta = w^3 + w^5 + w^6$$

(iii)

$$\alpha + \beta = -a$$

$$\Rightarrow a = -(w + w^2 + w^4 + w^3 + w^5 + w^6)$$

$$= -1 \quad (\text{using (i)})$$

$$= 1$$

1 correct answer for
a

$\alpha\beta = b$ $= (w + w^2 + w^4).(w^3 + w^5 + w^6)$ $= w^4 (1 + w + w^3).(1 + w^2 + w^3)$ $= w^4 (1 + w^2 + w^3 + w + w^3 + w^4 + w^3 + w^5 + w^6)$ $= w^4 (1 + w + w^2 + + w^6 + 2w^3)$ $= w^4 (0 + 2w^3)$ $= 2w^7 = 2$ $\therefore \quad \quad b = 2$	1 correct answer for b
(iv) Hence the quadratic equation is $x^2 + x + 2 = 0$ $x = \frac{-1 \pm \sqrt{1 - 4 \times 1 \times 2}}{2}$ $= \frac{-1 \pm i\sqrt{7}}{2}$ $\therefore \operatorname{Im} \alpha = \pm \frac{\sqrt{7}}{2}$ Now, $\operatorname{Im} \alpha = \operatorname{Im}(w + w^2 + w^4)$ $= \sin \frac{2\pi}{7} + \sin \frac{4\pi}{7} + \sin \frac{8\pi}{7}$ $= \sin \frac{2\pi}{7} + \sin \left(\pi - \frac{3\pi}{7} \right) + \sin \left(\pi + \frac{\pi}{7} \right)$ $= -\sin \frac{\pi}{7} + \sin \frac{2\pi}{7} + \sin \frac{3\pi}{7}$ $= \frac{\sqrt{7}}{2}$	1 Finding the roots of $x^2 + x + 2 = 0$ 1 expressing $\operatorname{im} \alpha$ 1 simplifying to achieve the result
