So when $v=0$, $x = 10 \ln 3$.

So the maximum height is $10 \ln 3$ metres.

(ii) When $x = 5 \ln 3$, $5 \ln 3 = 10 \ln \left(\frac{600}{200 + v^2} \right)$

$$e^{\frac{1}{2} \ln 3} = \frac{600}{200 + v^2} \quad \checkmark$$

$$\frac{200 + v^2}{600} = \frac{1}{\sqrt{3}}$$

$$200 + v^2 = 200\sqrt{3}$$

$$v^2 = 200(\sqrt{3} - 1) = 146.41 \dots$$

Let $u = (1 + \ln x)^n$.

(i) $\angle APB = \frac{\pi}{2}$, so it is an angle in a semicircle with diameter AB.

So M is the centre of the semicircle.

So AM and PM are equal radii. ✓

(ii) $AM = PM$ (from (i)),

so $\angle APM = \alpha$ (base angles of isosceles triangle), } ✓

so $\angle CPQ = \alpha$ (vertically opposite).

Now, $\angle ABD = \frac{\pi}{2} - \alpha$ (angle sum of $\triangle APB$), ✓

so $\angle ACD = \frac{\pi}{2} - \alpha$ (angles at circumference on same arc) } ✓

so $\angle MQC = \frac{\pi}{2}$ (angle sum of $\triangle PQC$). } ✓

So $MQ \perp DC$.

(15)(b)

(10)

(i) $\vec{OC}$ is the anticlockwise rotation of $\vec{OA}$ through $\frac{\pi}{3}$ about O. So $w_2 = w_1 \cdot 1 \operatorname{cis} \frac{\pi}{3}$
 $= w_1 \operatorname{cis} \frac{\pi}{3}$.

(ii) $\vec{OB}$ represents $w_1 + w_2 = w_1 + w_1 \operatorname{cis} \frac{\pi}{3}$
 $= w_1 (1 + \operatorname{cis} \frac{\pi}{3})$

and $\vec{AC}$ represents $w_2 - w_1 = w_1 \operatorname{cis} \frac{\pi}{3} - w_1$
 $= w_1 (\operatorname{cis} \frac{\pi}{3} - 1)$.

$$\begin{aligned}
 \text{(iii)} \quad i(w_1 + w_2) &= iw_1 (1 + \operatorname{cis} \frac{\pi}{3}) \\
 &= iw_1 \left(\frac{3}{2} + \frac{\sqrt{3}}{2} i \right) \\
 &= w_1 \left(-\frac{\sqrt{3}}{2} + \frac{3}{2} i \right) \\
 &= \sqrt{3} w_1 \left(-\frac{1}{2} + \frac{\sqrt{3}}{2} i \right) \\
 &= \sqrt{3} w_1 (\operatorname{cis} \frac{\pi}{3} - 1) \\
 &= \sqrt{3} (w_2 - w_1)
 \end{aligned}$$

$$\text{So } w_2 - w_1 = \frac{1}{\sqrt{3}} i (w_1 + w_2).$$

$$\text{So } w_2 - w_1 = (w_1 + w_2) \cdot r \operatorname{cis} \frac{\pi}{2}, \text{ where } r = \frac{1}{\sqrt{3}}.$$

So AC and OB are perpendicular.

$$(i) \frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \frac{b \sec^2 \theta}{a \sec \theta \tan \theta} = \frac{b \sec \theta}{a \tan \theta}$$

So the tangent at P has equation

$$y - b \tan \theta = \frac{b \sec \theta}{a \tan \theta} (x - a \sec \theta) \quad \checkmark$$

$$ay \tan \theta - ab \tan^2 \theta = bx \sec \theta - ab \sec^2 \theta$$

$$bx \sec \theta - ay \tan \theta = ab$$

(ii) Solve the tangent equation simultaneously with $y = \frac{bx}{a}$:

$$bx \sec \theta - bx \tan \theta = ab$$

$$x = \frac{a}{\sec \theta - \tan \theta} \cdot \frac{\sec \theta + \tan \theta}{\sec \theta + \tan \theta} = a(\sec \theta + \tan \theta)$$

$$\text{So } A = (a(\sec \theta + \tan \theta), b(\sec \theta + \tan \theta)) \quad \checkmark$$

$$\text{Similarly, } B = (a(\sec \theta - \tan \theta), b(\sec \theta - \tan \theta)) \quad \checkmark$$

$$\text{So } OA^2 \cdot OB^2 = (a^2(\sec \theta + \tan \theta)^2 + b^2(\sec \theta + \tan \theta)^2) \cdot (a^2(\sec \theta - \tan \theta)^2 + b^2(\sec \theta - \tan \theta)^2)$$

$$= (a^2 + b^2)(\sec \theta + \tan \theta)^2 \cdot (a^2 + b^2)(\sec \theta - \tan \theta)^2 \quad \checkmark$$

$$= (a^2 + b^2)^2 (\sec^2 \theta - \tan^2 \theta)^2$$

$$\text{So } OA \cdot OB = a^2 + b^2$$

(15)(c)(iii) $OA \cdot OA' = OB \cdot OB'$, by the definitions of A' and B' .

So, by the converse of the intersecting chords theorem, the points A, B, A' and B' are concyclic. ✓

$$(iv) OA \cdot OA' = OB \cdot OB'$$

$$= OA \cdot OB$$

So, by the converse of the intersecting chords theorem, S and S' lie on the same circle as A, B, A' and B' .

(iii) Let $n=3$.

Then $(2 \cos 6\theta + 2 \cos 4\theta + 2 \cos 2\theta + 1) \sin \theta = \sin 7\theta$

$2(4 \cos^3 2\theta - 3 \cos 2\theta) + 2(2 \cos^2 2\theta - 1) + 2 \cos 2\theta + 1 = \frac{\sin 7\theta}{\sin \theta}$
 $8 \cos^3 2\theta + 4 \cos^2 2\theta - 4 \cos 2\theta - 1 = \frac{\sin 7\theta}{\sin \theta}$

(iv) Let $\theta = \frac{\pi}{7}$.

(ii) Proof by induction:

When $n=2$, LHS = $2 \times \frac{4}{3} = 2\frac{2}{3}$ and RHS = $3 \times \frac{3}{4} = 2\frac{1}{4}$.

So the result is true when $n=2$.

Assume that the result is true for the positive integer $n=k$.

That is, assume that $k(1 + \frac{1}{3} + \dots + \frac{1}{2k-1}) > (k+1)(\frac{1}{2} + \frac{1}{4} + \dots + \frac{1}{2k})$. (*)

Prove that the result is true for $n=k+1$.
